RESEARCH MEMORANDUMTHE FORCES AND PRESSURE DISTRIBUTION AT SUBSONIC SPEEDS
ON A PLANE WING HAVING 45° OF SWEETBACK, AN ASPECT
RATIO OF 3, AND A TAPER RATIO OF 0.5

By Carl D. Kolbe and Frederick W. Boltz

SUMMARY

An investigation was conducted to determine the effects of scale and compressibility on the forces, moments, and pressure distribution on a wing having an aspect ratio of 3 and a taper ratio of 0.5. The line joining the quarter-chord points of the airfoil sections was swept back 45° and the airfoil sections perpendicular to this line were the NACA 64A010.

Lift, drag, and pitching-moment data and the chordwise distribution of static pressure at seven spanwise stations are presented for Reynolds numbers up to 18,000,000 at a constant Mach number of 0.25; for Mach numbers ranging from 0.08 to 0.96 at a constant Reynolds number of 4,000,000; and for Mach numbers of 0.08, 0.25, and 0.60 at a constant Reynolds number of 8,000,000.

It was indicated from the force and moment data that, for all Mach numbers and Reynolds numbers in the test range, no apparent flow separation existed near the leading edge of the wing for lift coefficients less than 0.3. At higher lift coefficients, the initiation of flow separation and reattachment near the leading edge of the outer sections of the wing was generally accompanied by an increase in the lift-curve slope, a rearward movement of the aerodynamic center, and an increase in the rate of drag rise.

The effect of increasing the Reynolds number was to delay to higher lift coefficients the onset of leading-edge flow separation and the concomitant effects on the lift, drag, and pitching moment.

Increasing the Mach number to approximately that for drag divergence at a Reynolds number of 4,000,000 resulted in a rearward movement of

the wing aerodynamic center of about 6 percent at the mean aerodynamic chord at zero lift.

The effects of compressibility on the force and moment characteristics up to a Mach number of 0.60 were influenced by an increase in Reynolds number from 4,000,000 to 8,000,000. At the lower Reynolds number, the angle-of-attack range for which the lift and pitching-moment curves were nearly linear was reduced by the increase in Mach number, whereas this angle-of-attack range was increased at the higher Reynolds number.

An investigation of several types of juncture arrangements between the model and the turntable indicated that varying the type of seal caused but little change in the forces, moments, and pressure distribution on the model.

INTRODUCTION

Wings having moderately high degrees of sweepback offer the possibility of flight at transonic speeds without serious compressibility effects. Studies of the pressure distributions on such wings have shown that simple sweep theory does not offer an adequate method of predicting the chordwise distribution of pressure near the roots or the tips of the wings. For swept-back wings of low aspect ratio, a substantial part of the wing surface is subjected to flow characteristics which result from the so-called root and tip effects. Experimental determination of the pressure distribution on such wings will provide not only detailed information concerning the aerodynamic characteristics, but also will furnish data for evaluating and extending the theoretical methods for computing surface pressures.

An investigation has been conducted in the Ames 12-foot pressure wind tunnel throughout a wide range of Reynolds numbers and subsonic Mach numbers to obtain experimentally the pressure distribution and the total lift, drag, and pitching moment on a wing having 45° of sweepback and an aspect ratio of 3. To determine the effects of both Mach number and Reynolds number, the wing was tested at constant Reynolds numbers over a range of Mach numbers and at a constant Mach number over a range of Reynolds numbers. The force data and a representative portion of the pressure data are presented in graphic form along with a limited analysis of the data. The complete pressure data for the wing are presented in tabular form.

NOTATION

a_0 speed of sound in free stream, feet per second

$\frac{b}{2}$ semispan, measured perpendicular to plane of symmetry, feet

c_D drag coefficient $\left(\frac{\text{drag}}{q_0 S} \right)$

M_0 free-stream Mach number $\left(\frac{V_0}{a_0} \right)$

P local pressure coefficient $\left(\frac{p - p_0}{q_0} \right)$

p local static pressure, pounds per square foot

p_0 free-stream static pressure, pounds per square foot

q_0 free-stream dynamic pressure $\left(\frac{1}{2} \rho_0 V_0^2 \right)$, pounds per square foot

R Reynolds number $\left(\frac{\rho_0 V_0 C}{\mu_0} \right)$

S semispan wing area, square feet (using theoretical tip chord)

V_0 free-stream velocity, feet per second

y lateral distance perpendicular to the plane of symmetry, feet

α angle of attack, degrees

α_u angle of attack uncorrected for tunnel-wall interference and angle-of-attack counter correction, degrees

η fraction of semispan $\left(\frac{y}{b/2} \right)$

μ_0 coefficient of viscosity of air, slugs per foot-second

ρ_0 free-stream mass density of air, slugs per cubic foot

MODEL AND APPARATUS

The model wing used in this investigation had the leading edge swept back 48.54° , an aspect ratio of 3.0, and a taper ratio of 0.5. The wing had no twist and the sections were the NACA 64AO10 in planes inclined 45° to the plane of symmetry. The locus of the quarter-chord points of these sections was swept back 45° . This line was at 29.63 percent of the chord parallel to the plane of symmetry. The tip of the wing was formed by a half body having a radius equal to the corresponding half thickness of the tip section. Coordinates of the NACA 64AO10 section and of the sections parallel to the plane of symmetry are presented in tables I and II, respectively.

The model, which had a semispan of 46.67 inches, was constructed of a tin-bismuth alloy bonded to a laminated steel spar. Pressure orifices were installed in seven rows in planes parallel to the plane of symmetry. The orifices were distributed along the chord on both the upper and lower surfaces from the leading edge to the 91-percent-chord point and were staggered $1/4$ inch on either side of the station planes. A sketch of the plan form of the wing showing the locations of the seven orifice rows and the manner in which the orifices were staggered is given in figure 1. The locations of the orifices along the chord at each station are given with the tabulated pressure-coefficient data (tables III through XXII).

Figure 2 shows the model mounted in the wind-tunnel test section. The test-section floor served as a reflection plane. The forces and moments were transmitted directly to the balance system through the turn-table upon which the model was mounted. Pressures were measured by means of multiple-tube manometers and were recorded photographically.

Twenty-six flush orifices were installed in the wind-tunnel test section for the purpose of investigating the onset and the extent of supersonic flow along the tunnel wall opposite the upper surface of the model. The location of these orifices with respect to the model is illustrated in figure 3.

Cross-sectional views of the juncture arrangements between the model and the turntable that were used in the investigation of various seals are shown in figure 4. It is to be noted that the configurations shown in figure 4 extended completely around the root section of the model.

TESTS

The chordwise distributions of pressure at seven sparwise stations on the wing were measured simultaneously with the total lift, drag, and

pitching moment at Reynolds numbers of 4,000,000, 6,000,000, 8,000,000, 12,000,000, and 18,000,000 for a Mach number of 0.25. Similar measurements were made at a Reynolds number of 4,000,000 for Mach numbers ranging from 0.08 to 0.96 and at a Reynolds number of 8,000,000 for Mach numbers of 0.08 and 0.60. The angle of attack was varied from -2° to 30° during the low-speed tests, but this range was reduced at the higher Mach numbers where wind-tunnel power limitations prevented testing at the higher angles of attack. At Reynolds numbers of 12,000,000 and 18,000,000, the capacity of the wind-tunnel balance system limited the force measurements to angles of attack of 28° and 16° , respectively.

Surface pressures on the tunnel wall were measured in the vicinity of the model to ascertain the test conditions at which the data may have been affected by wind-tunnel choking.

As an adjunct to the basic tests, an investigation was made to determine the effect of various seals at the model-turtable juncture on the measured forces, moments, and pressures on the model. For each of the six arrangements shown in figure 4, measurements of the lift, drag, pitching moment, and static pressures on the wing were obtained for Mach numbers of 0.25 and 0.80 at a constant Reynolds number of 4,000,000. The seal arrangement denoted as "original" was used throughout the general investigation of the wing aerodynamic characteristics.

CORRECTIONS TO DATA

Corrections to the data for tunnel-wall interference resulting from lift on the model were evaluated by the method of reference 1 using the theoretical span loading derived from the charts of reference 2. The following increments were added to the angle of attack and drag coefficient:

$$\Delta\alpha = 0.769 C_L \text{, degrees}$$

$$\Delta C_D = 0.0109 C_L^2$$

No corrections were applied to the pitching-moment data.

The pressure data and the coefficients derived therefrom are presented in this report for values of uncorrected angle of attack α_u . The relation between the corrected and uncorrected angles of attack is as follows:

$$\alpha = 0.99 \alpha_u + \Delta\alpha$$

Corrections for the effects of constriction were evaluated by the method of reference 3. This method, while not accounting for sweepback and being strictly applicable only to full-span models centrally located in the tunnel, has been used as the best available estimate of the constriction effects. The magnitude of the corrections applied to the free-stream Mach number and to the dynamic pressure is illustrated in the following table:

Corrected Mach number	Uncorrected Mach number	$\frac{\text{Corrected } q_0}{\text{Uncorrected } q_0}$
0.08	0.080	1.001
.25	.250	1.003
.60	.599	1.004
.80	.795	1.008
.90	.888	1.014
.92	.905	1.018
.94	.920	1.022
.96	.934	1.054

The following corrections were subtracted from the drag coefficients to compensate for the forces on the exposed surface of the turntable:

$R \times 10^{-6}$	M_∞	C_{D_t}
4.0	0.08	0.0027
	.25	.0028
	.60	.0030
	.80	.0033
	.90	.0036
	.92	.0037
	.94	.0038
	.96	.0040
6.0	.25	.0026
8.0	.08	.0023
	.25	.0024
	.60	.0025
12.0	.25	.0023
18.0	.25	.0022

No attempt was made to evaluate the tares due to possible interference between the model and the turntable or to compensate for the tunnel-floor boundary layer which, at the model, had a displacement thickness of 1/2 inch. The magnitude of these effects is believed to be small.

Through consideration of the results of the static loading tests on a model of moderate aspect ratio presented in reference 4 and the greater

structural rigidity of the subject model, it was assumed that the effects of aeroelasticity on the aerodynamic characteristics of the model were negligible.

RESULTS AND DISCUSSION

The surface pressures on the model, measured for the complete range of Mach numbers and Reynolds numbers at selected angles of attack, are presented as pressure coefficients in tabular form immediately following the figures. Table III is an index to these data which are presented in tables IV through XXII. A representative portion of the pressure-distribution data has been presented graphically in the figures of this report to facilitate the analysis of the force and moment characteristics of the model. Due to the staggering of the orifices (as explained in the section "Model and Apparatus"), a slight "saw-tooth" variation is present in the plotted values of the chordwise pressure distributions, particularly in regions where the spanwise pressure gradients were large. A mean fairing through the plotted values of pressure coefficient was therefore used to represent the pressure distribution at the spanwise stations indicated in figure 1.

The results of an investigation that was made to ascertain the effect of model-turntable juncture seals are presented in the appendix. These data indicate that the various alterations to the seal, in the model-turntable juncture, produced no significant changes in the aerodynamic characteristics of the wing.

Effects of Reynolds Number at a Mach Number of 0.25

The lift, drag, and pitching-moment characteristics of the model are presented in figure 5 for Reynolds numbers of 4,000,000, 8,000,000, 12,000,000, and 18,000,000. Figure 6 presents the chordwise distributions of pressure coefficient at the seven spanwise stations for several angles of attack at Reynolds numbers of 4,000,000, 8,000,000, and 18,000,000. Inspection of figure 5(a) reveals that at low to moderate values of lift coefficient the variation of lift coefficient with angle of attack was linear and the lift-curve slope was little affected by the increase in Reynolds number. At a Reynolds number of 4,000,000 the lift-curve slope increased beyond a lift coefficient of about 0.4 and decreased at lift coefficients greater than about 0.75. A comparison of these data with the pressure data in figure 6 indicates that the increase in lift-curve slope was due to separation and reattachment of the flow near the leading edge of the outer sections (indicated by a reduction in the peak pressure coefficients). Further comparison of the data shows that the reduction in the lift-curve slope occurred when the

separated flow failed to reattach over the outer sections (indicated by a chordwise distribution of nearly constant pressure). Increasing the Reynolds number above 4,000,000 resulted in an increase in the lift coefficient at which the lift-curve slope increased and an increase in the lift coefficient at which complete flow separation over the outer sections resulted in a decrease in the lift-curve slope. The maximum lift coefficient increased only slightly as the Reynolds number was increased from 4,000,000 to 12,000,000.

The increase in lift-curve slope at moderate angles of attack was accompanied by a rearward movement of the wing center of pressure (fig. 5(b)) which was followed by a forward movement as the lift-curve slope decreased. Beyond maximum lift the wing center of pressure moved rearward. With increasing Reynolds number the initiation of flow separation over the outer sections had a more pronounced effect on the rearward movement of the wing center of pressure.

Inspection of the drag data in figure 5(c) in conjunction with the lift and moment data in figures 5(a) and 5(b) shows that an additional increase in the rate of change of drag coefficient with lift coefficient occurred simultaneously with the increase in lift-curve slope and longitudinal stability.

In figure 7 the section normal-force coefficients, derived from integration of the pressure data, are presented as functions of the uncorrected angle of attack. With increasing Reynolds number there was an increase in the maximum section normal-force coefficients at the outer sections. A comparison of the data of figure 7 with that presented in figure 5 indicates that the increase in the lift-curve slope, the increase in longitudinal stability, and the more rapid rate of drag rise of the wing coincided with the increase in the section normal-force-curve slope of the tip sections. Attendant upon this increase in the section normal-force-curve slope at the higher Reynolds number was a rapid expansion of the chordwise extent of the region of flow separation starting from just behind the leading edge. The resultant redistribution of pressure caused a rearward movement of the centers of pressure of the outer sections as shown in figure 8.

Effects of Reynolds Number at a Mach Number of 0.60

The lift, drag, and pitching-moment characteristics of the wing are compared in figure 9 for Reynolds numbers of 4,000,000 and 8,000,000. The corresponding chordwise distributions of static pressure coefficient at the seven spanwise stations are presented in figure 10 for several angles of attack. From figure 9 it is evident that increasing the Reynolds number from 4,000,000 to 8,000,000 extended the linear portion of the lift curve, caused a more nearly linear variation of the pitching-moment coefficient with the lift coefficient, and resulted in a reduction

in the drag coefficients for lift coefficients greater than about 0.2. The pressure data in figure 10 reveal that at the higher Reynolds number there was an increase in the angle of attack at which the reduction in the peak pressure coefficients began at the outer sections. These data also show that at the higher Reynolds number there was a more gradual reduction in the peak pressure coefficients near the leading edge of the wing with increasing angle of attack, probably the result of a more gradual growth of the chordwise extent of the region of separation.

In figure 11 the section normal-force coefficients at the two Reynolds numbers are presented as functions of the uncorrected angle of attack. The effect of increasing the Reynolds number was to delay to higher angles of attack the rapid increase in section normal-force coefficient and also to increase the maximum values of section normal-force coefficient at the outer sections. A comparison of figures 10 and 11 reveals that at a Reynolds number of 4,000,000 the large increase in slope of the section normal-force curves was the result of the region of separation extending a considerable distance rearward from the leading edge. At a Reynolds number of 8,000,000 the onset of separation and reattachment of the flow near the leading edge was, for most sections, at first accompanied by a decrease in the slope of the section normal-force curves followed by an increase in the slope as the region of separation extended rearward from the leading edge.

In addition to the changes in the section normal-force coefficients with the increase in Reynolds number, the positions of the section centers of pressure were also changed. The variations of the locations of the section centers of pressure and of the pitching-moment coefficient of the wing with angle of attack at Reynolds numbers of 4,000,000 and 8,000,000 are shown in figure 12. It is to be noted that the rearward movement of the section centers of pressure was considerably more abrupt and of greater magnitude at a Reynolds number of 4,000,000 than at a Reynolds number of 8,000,000. Thus, it appears that changes in the section centers of pressure as well as changes in the spanwise distribution of the section normal-force coefficient were responsible for the differences noted in the pitching-moment characteristics at these two Reynolds numbers.

Effects of Mach Number at a Reynolds Number of 4,000,000

Limitations of the data due to wind-tunnel choking.—Before the effects of Mach number on the aerodynamic characteristics are discussed, it is necessary to explain the possible limitations of portions of the data obtained at Mach numbers near those at which choking occurred in the wind tunnel. In order to ascertain the degree of wind-tunnel choking, static pressures were measured along the wind-tunnel wall

opposite the upper surface of the model. From these pressure surveys the approximate extent of supersonic flow on the tunnel wall was determined.

As an illustration of the results of the surveys, figure 13 is presented. This figure shows the development of a region of supersonic flow on the upper surface of the model and on the tunnel wall with increasing angle of attack at a Mach number of 0.92. It is apparent that, at angles of attack of 4° or less, the extent of supersonic flow on the tunnel wall was small and, consequently, any alteration to the supersonic flow field about the model due to the presence of the tunnel walls was probably slight. However, as the angle of attack was increased to 6° and beyond, the region of supersonic flow on the tunnel wall increased, resulting in a "partially choked" condition. The data obtained under these conditions are represented by the dotted portions of the curves in the figures.

Force and moment characteristics.— In figure 14 the aerodynamic characteristics of the wing at Mach numbers ranging from 0.08 to 0.96 are presented for a constant Reynolds number of 4,000,000. Included in this figure are the data obtained at Mach numbers of 0.08, 0.25, and 0.60 for a constant Reynolds number of 8,000,000. These data will be discussed under the heading "Influence of Reynolds Number on the Effects of Compressibility." The effects of Mach number on the lift, drag, and pitching-moment coefficients at a Reynolds number of 4,000,000 are summarized in figures 15 and 16 wherein the coefficients are plotted as functions of Mach number. The variation with Mach number of the lift-curve slope and the locations of the aerodynamic center for several angles of attack are shown in figures 17 and 18, respectively. The maximum lift-drag ratio and the lift coefficient for maximum lift-drag ratio are presented in figure 19.

With reference to figure 14(a), it may be seen that the lift-curve slope increased at lift coefficients of 0.6 and 0.4 for Mach numbers of 0.08 and 0.25, respectively, whereas the increase in lift-curve slope began at a lift coefficient of about 0.3 for Mach numbers from 0.40 to 0.90. In figure 17 the theoretical value of lift-curve slope computed by the method of reference 2 is shown in comparison with the experimental values for lift coefficients of 0, 0.2, and 0.4. The agreement between the experimental and theoretical values is good for lift coefficients of 0 and 0.2. The marked increase in the experimental values at a lift coefficient of 0.4 is believed to have resulted from separation and reattachment of the flow near the leading edge of the tip of the wing.

In figure 15, the pitching-moment coefficients for constant values of lift coefficient at a Reynolds number of 4,000,000, obtained from figure 14(b), are shown to have gradually become more negative with increasing Mach number. At Mach numbers slightly below those where the

tunnel became partially choked the pitching-moment coefficients increased rapidly in absolute value.

The effect of Mach number on the location of the aerodynamic center at angles of attack of 0° , 2° , 4° , and 6° , is shown in figure 18. The aerodynamic center at an angle of attack of 0° moved rearward approximately 6 percent of the mean aerodynamic chord as the Mach number was increased from 0.08 to 0.92 and then moved rapidly rearward as the Mach number was further increased. At angles of attack of 2° and 4° , the position of the aerodynamic center varied only slightly up to Mach numbers of 0.91 and 0.90, respectively, beyond which it moved rapidly rearward. At an angle of attack of 6° , the aerodynamic center moved aft approximately 9 percent of the mean aerodynamic chord as the Mach number was increased from 0.08 to 0.85 and then continued rearward more rapidly with increasing Mach number.

In figure 14(c), the familiar low-drag range is discernible at low lift coefficients at Mach numbers up to 0.83. The loss of this low-drag region is reflected in the lower two curves shown in figure 16 wherein the drag coefficient is presented as a function of Mach number for constant values of lift coefficient. At a Mach number of 0.83 the drag coefficient may be seen to have increased only slightly over its low-speed value for lift coefficients of 0 and 0.1. Between a Mach number of 0.83 and that for drag divergence the drag increased roughly 50 percent. A similar variation of the drag coefficient with Mach number may be noted for a lift coefficient of 0.2 although this was outside the low-drag range. At higher lift coefficients the gradual drag rise commenced at considerably lower Mach numbers. The Mach number for drag divergence, defined as the point at which $(\partial C_D / \partial M_0)_{C_L} = 0.10$, decreased from about 0.94 at a lift coefficient of 0 to 0.875 at a lift coefficient of 0.5. The sudden reduction in drag coefficient just prior to drag divergence for lift coefficients of 0.4 and 0.5 may be due to a reduction in the region of separated flow over the forward part of the airfoil as explained in reference 5.

In figure 19 the maximum lift-drag ratio is shown to have been about 19 between Mach numbers of 0.08 and 0.45, thereafter decreasing gradually to about 16 at a Mach number of 0.92. Further increase in Mach number up to 0.96 resulted in a decrease in the maximum lift-drag ratio to about 9. The lift coefficient for maximum lift-drag ratio deviated only slightly from 0.2 throughout the Mach number range.

Pressure-distribution characteristics.— The chordwise distribution of pressure coefficient at the seven spanwise stations is presented in figure 20 for angles of attack of 2° , 4° , and 6° at several selected Mach numbers. The pressure distributions for an angle of attack of 2° were used in locating the isobars, or lines of constant pressure coefficient, on the upper and lower surfaces of the model as shown in figure 21. It can be seen that, in general, the isobars curve rearward near the root of the wing so as to approach the plane of symmetry

perpendicularly. Conversely, the isobars at the tip of the wing tend to curve forward. From the isobar plots it may be seen that the points of minimum pressure, exclusive of those at or near the leading edge, were displaced rearward at sections near the root and forward at sections near the tip. The crest lines (lines defining the locus of points at which the surface of the wing is tangent to the undisturbed free stream) are indicated in figure 21 to provide a reference from which to gage the variance in the isobars. A discussion of an interpretation of isobars is given in reference 4.

The spanwise distributions of section normal-force coefficient at several Mach numbers are presented in figure 22 for angles of attack of 2° , 4° , and 6° . As previously noted, the dotted curves represent data obtained with the supersonic flow field of the model extending to the tunnel wall. It may be observed that the maximum value of section normal-force coefficient occurred at about 70 percent of the semispan. As the Mach number was increased from 0.60 to 0.90 at an angle of attack of 6° , the section normal-force coefficient showed a greater increase at the tip stations than at stations nearer the root. This greater increase in the section normal-force coefficient of the tip sections was accompanied by an increase in the lift-curve slope, an increase in stability, and an increase in the rate of drag rise. (See fig. 14.)

In figure 23 the spanwise distribution of loading coefficient $c_{nc}/CN c_{av}$ at several Mach numbers is presented in comparison with the theoretical distribution. The theoretical distribution is practically invariant throughout the range of Mach numbers for which experimental data are presented. Similarly, the experimental values of loading coefficient show only small variations with Mach number and are in good agreement with the theoretical values. The experimental loading coefficients are based upon the slopes of the section normal-force curves measured through an angle of attack of 0° .

The effects of compressibility on the locations of the section centers of pressure at the seven spanwise stations for angles of attack of 2° , 4° , and 6° are shown in figure 24. The effect of increasing Mach number was, generally, to cause a rearward movement of the section centers of pressure near the root and a forward movement near the tip up to approximately the Mach number for drag divergence. An exception to this variation with Mach number is shown for an angle of attack of 6° at 0.924 semispan where the center of pressure moved rearward with increasing Mach number. The over-all effect of the movements of the section centers of pressure, together with the changes in the spanwise distribution of load (fig. 22), on the location of the wing aerodynamic center at angles of attack of 2° , 4° , and 6° may be seen by reference to figure 18.

Influence of Reynolds Number on the Effects of Compressibility

In figure 14, the data obtained at several Mach numbers for a Reynolds number of 8,000,000 have been included with the data for a Reynolds number of 4,000,000 to show, insofar as is possible, the influence of Reynolds number on the compressibility effects encountered up to a Mach number of 0.60.

With an increase in Mach number to 0.60, the linear portion of the lift curve (fig. 14(a)) was extended to higher lift coefficients at a Reynolds number of 8,000,000, whereas at a Reynolds number of 4,000,000 it was reduced. This same trend may be seen in the pitching-moment characteristics (fig. 14(b)) where changes in stability with an increase in Mach number to 0.60 were delayed to higher lift coefficients at a Reynolds number of 8,000,000, whereas at a Reynolds number of 4,000,000 increasing the Mach number to 0.60 reduced the lift coefficient at which changes in stability occurred. Thus, the effect of increasing Mach number on the lift coefficient at which tip stalling occurred was apparently reversed by increasing the Reynolds number from 4,000,000 to 8,000,000. The drag data (fig. 14(c)) indicate, however, that an increase in the rate of change of drag coefficient with lift coefficient occurred at about the same lift coefficient for Reynolds numbers of 4,000,000 and 8,000,000 at a Mach number of 0.60. The explanation of this effect of Reynolds number is provided in the pressure data of figure 10. These data show that at a Reynolds number of 8,000,000, leading-edge flow separation with reattachment near the tip of the wing actually began at an angle of attack between 6° and 8° although the flow did not separate completely over the outer sections until the angle of attack was increased beyond 12° . At a Reynolds number of 4,000,000 the flow had separated completely over the outer sections at an angle of attack of 8° . Thus, due to the more gradual spreading of the stall near the tip at a Reynolds number of 8,000,000, there was no sudden change in the slope of either the lift curve or the pitching-moment curve although the drag rise was similar to that at a Reynolds number of 4,000,000.

It is important to note that the favorable effects of increasing the Reynolds number may persist at still higher Mach numbers. In this event, the effect of increasing Mach number at higher Reynolds numbers would differ from that shown at a Reynolds number of 4,000,000.

CONCLUSIONS

An investigation has been made of the effects of scale and compressibility on the aerodynamic characteristics of a wing having the quarter-chord line swept back 45° and an aspect ratio of 3.0. Force, moment, and surface pressures were measured for Reynolds numbers up

to 18,000,000 at a constant Mach number of 0.25; for Mach numbers up to 0.96 at a constant Reynolds number of 4,000,000; and for Mach numbers up to 0.60 at a constant Reynolds number of 8,000,000. The results of the tests indicate the following conclusions:

1. For all Mach numbers and Reynolds numbers in the test range, no flow separation appeared to exist near the leading edge of the wing for lift coefficients less than 0.3. At higher lift coefficients the initiation of leading-edge flow separation with reattachment, over the outer portions of the wing, was accompanied in nearly every case by an increase in the lift-curve slope, an increase in static longitudinal stability, and an increase in the rate of drag rise.
2. The effect of increasing the Reynolds number at Mach numbers of 0.25 and 0.60 was to delay to higher lift coefficients the onset of flow separation near the leading edge and the concomitant effects on the lift, drag, and pitching moment.
3. Increasing the Mach number to approximately that for drag divergence at a Reynolds number of 4,000,000 resulted in a rearward movement of the wing aerodynamic center of about 6 percent of the mean aerodynamic chord at zero lift. (The Mach number for drag divergence was found to vary from about 0.94 at a lift coefficient of 0 to about 0.875 at a lift coefficient of 0.5.) Further increase in Mach number resulted in a rapid rearward movement of the aerodynamic center.
4. The spanwise distribution of loading coefficient at low lift coefficients showed good agreement with theory, being practically unaffected by compressibility. The increase in lift-curve slope with Mach number also was in good agreement with that predicted by theory.
5. The effects of compressibility on the force and moment characteristics up to a Mach number of 0.60 were influenced by an increase in Reynolds number from 4,000,000 to 8,000,000. At the lower Reynolds number the angle-of-attack range for which the lift and pitching-moment curves were nearly linear was reduced by the increase in Mach number, whereas this angle-of-attack range was increased at the higher Reynolds number.
6. Various alterations to the seal at the model-turntable juncture produced no significant changes in the aerodynamic characteristics of the wing.

APPENDIX

MODEL-TURNTABLE SEAL INVESTIGATION

In wind-tunnel testing with semispan models it would be desirable to isolate the reflection-plane turntable from the force-measuring apparatus. Such an arrangement poses the problem of minimizing air flow through the model-turntable juncture in such a manner that the flow over the model is not disturbed and the turntable acts as a true reflection plane. To ascertain the effects of various model-turntable-juncture seal arrangements on the measured forces, moments, and pressures, six seals were tested. These seal arrangements are illustrated in figure 4.

In figure 25 the lift, drag, and pitching-moment data for each of the five modified seal arrangements have been superimposed on the corresponding data for the original seal arrangement. Data are shown for Mach numbers of 0.25 and 0.80 at a constant Reynolds number of 4,000,000.

From the nature of the different configurations, it might be expected that the greatest difference in the force characteristics of the model would appear in changing from seal A to seal B. (See fig. 4). However, the data presented in figure 25 indicate that only small changes in the forces and moments resulted in changing from any one arrangement to any other. The slight differences which do exist in the force and moment data could be attributable to experimental scatter rather than to changes in the flow at the root of the wing.

Further evidence of the negligible effect of the various seal modifications is indicated in figure 26 wherein is shown a comparison of the chordwise distribution of pressure coefficient for an angle of attack of 16° at 0.086 semispan for seals A and B. The data for a rerun with seal A are included to indicate the variation in pressures which might be expected from the experimental variations. From the data in figure 26, it was found that in changing from seal A to seal B the section normal-force coefficient at 0.086 semispan decreased about 1 percent at a Mach number of 0.25 and about 3 percent at a Mach number of 0.80. The decrease in section normal-force coefficient was smaller at the remaining semispan stations so that the over-all effect was considered negligible.

Figure 1.-Plan form of the wing.

Figure 2.- The model mounted in the Ames 12-foot pressure wind tunnel.

Figure 3.—The location of the wall orifices in the Ames 12-foot pressure wind-tunnel test section.

Figure 4.—Cross sections of several seals at the base of the model.

Figure 5.-The effect of Reynolds number on the low-speed aerodynamic characteristics. $M_0 = 0.25$.

$$C_{L_1} = 2.865$$

Figure 5.—Continued.
(b) C_L vs C_m

Figure 6.—The chordwise distribution of pressure coefficient at seven semispan stations for several angles of attack and Reynolds numbers of 4,000,000, 8,000,000, and 18,000,000. $M_\infty = 0.25$.

Figure 6.-Continued.

Figure 6.-Concluded.

Figure 7.—The effect of Reynolds number on the section normal-force coefficients at seven semispan stations. $M_\infty, 0.25$.

$$\frac{C_n}{4.3} = 1.58$$

Figure 8.—The variation of the section centers of pressure and the pitching-moment coefficient with angle of attack for Reynolds numbers of 4,000,000, 8,000,000, and 18,000,000. M_∞ , 0.25.

Figure 9.—The aerodynamic characteristics at Reynolds numbers of 4,000,000 and 8,000,000. $M_a = 0.60$.

Figure 10.—The chordwise distribution of pressure coefficient at seven semispan stations for several angles of attack and Reynolds numbers of 4,000,000 and 8,000,000. M_∞ , 0.60.

(b) $\alpha_u, 6^\circ, 8^\circ, 10^\circ$

Figure 10.—Continued.

Figure 11.—The effect of Reynolds number on the section normal-force coefficients at seven semispan stations. $M_\infty, 0.60$.

Figure 12.—The variation of the section centers of pressure and the pitching-moment coefficient with angle of attack for Reynolds numbers of 4,000,000 and 8,000,000. M_∞ , 0.60.

Figure 13.—The development of supersonic flow on the upper surface of the model and on the tunnel wall with increasing angle of attack. M_∞ , 0.92; R , 4,000,000.

(b) C_L vs C_m

Figure 14--Continued.

(c) C_L vs C_D
Figure 14.-Concluded.

Figure 15.—The variation of the lift and pitching-moment coefficients with Mach number. $R, 4,000,000$.

Figure 16.—The variation of the drag coefficient with Mach number.
R, 4,000,000.

Figure 17.—The variation of the lift-curve slope with Mach number.
R, 4,000,000.

Figure 18.—The variation of the location of the aerodynamic center with Mach number. $R, 4,000,000$.

Figure 19.—The variation of the maximum lift-to-drag ratio and the lift coefficient for the maximum lift-to-drag ratio with Mach number.
 $R, 4,000,000$.

Figure 20.—The chordwise distribution of pressure coefficient at seven semispan stations for several Mach numbers. $R, 4,000,000$.

Figure 20.-Continued.

Figure 20.-Concluded.

Figure 21.—The lines of constant pressure coefficient on the upper and lower surfaces for several Mach numbers.
 $a_u, 2^\circ; R, 4,000,000.$

(b) $M_\infty, 0.90, 0.92, 0.94$ *Figure 21.-Concluded.*

Figure 22.—The spanwise distribution of section normal-force coefficient at several Mach numbers for three angles of attack. $R, 4,000,000$.

Figure 23.-The spanwise distribution of loading coefficient at several Mach numbers.
R, 4,000,000.

Figure 24.—The variation of the section centers of pressure with Mach number for three angles of attack. $R, 4,000,000.$

(a) C_L vs α

Figure 25.- The effect of various seals at the base of the model on the aerodynamic characteristics at Mach numbers of 0.25 and 0.80.
 $R, 4,000,000.$

(b) C_L vs C_m

Figure 25.—Continued.

Figure 25.-Concluded.

Figure 26.—The chordwise distribution of pressure coefficient at 0.086 $b/2$ for the model-turntable juncture seals A and B. α_u , 16° ; R , 4,000,000.
